Two recent studies focused on urban areas andcasualties but also with pedestrian casualtass. [estimated that across major cities in the USA, an Another country-level study found that busses were increase in the share of mass transit was associatedhore likely to kill pedestrians than cars and light with reduced motor vehicle fatalities, but the fatality trucks [26], but it used vehicle-miles as the measure rates were expressed asaliates per city residents of exposure instead of passengers-miles or individual trips, it includes all types of bus travel, and it did (as opposed to distance traveleta),[11]. However, in these city level studies, an ecological fallaty][not control for the volume of pedestrians, which cannot be ruled out: city level association between might be greater on urban bus routes.

public transit use and lower fatality rate may not be This work has two main objectives, to compare: (i) observed at the route level. In other words, from the rate of injury for car and city bus occupants on studies which find that bus is safer than car overall specific urban major roads and (ii) pedestrian and cyclist at the city level, we cannot speculate about the businjuries associated with car and bus travel.

Methods

The study environment is the island of Montreal (representing the number of weekdays in a year). (Canada), with a population of 1.8 million. Travel (STM).

Traffic Routes

Figure 1 shows the density of accidents involving a daily traffic (AADT). The daily number of vehicles on bus from which the STM professionals identified ten road sections-between intersections with vehicle routes with the highest number of injuries involving counts—was calculated by taking the sum of all vehicles for analysis and were divided into road sections, exiting at the next intersection. For two-way road secdefined by entry and exit points of bus routes. Road tions, this procedure was applied to both directions of sections which did not form part of a STM bus route vehicular traffic. The daily number of car occupants on a were excluded.

For every STM bus line, the number of persons vehicles on this section by the average number (1.23) of entering and exiting the bus was counted for all stopscar occupants in Montréal (based on the 2008 Originover a 24-h period, with automatic sensors installed on Destination Survey).

busses on a weekday, between September and Decem- For car and bus travel, passenger-kilometers were ber 2008 (data provided by STM). The daily number of obtained by multiplying the number of people traveling bus passengers per road section was obtained by addingn a road section by the length of the section. Then, the the number of passengers for each bus line traveling passenger-kilometers on each road section were

along the same road section. Travel by bus was converted to passengers per year by multiplying by 260 Vehicle counts (20022010) at intersections along by bus and metro (around 1.2 million trips per day) the ten selected routes were provided by the city of

are managed by the Société de transport de MontrealMontreal. The average daily number of vehicles was estimated for each vehicle direction (maximum 12 directions per intersection) using expansion factors (taking into account the time, day, and month of the vehicle count) traditionally used to produce the average annual a bus (20072010). These ten routes were selected entering the section and subtracting all the vehicles road section was obtained by multiplying the number of

To compare the safety of travel by car and by city and city bus occupant injuries is calculated as shown in kilometers). Eq. 3a The rate ratios used to compare pedestrian (or cyclist) injuries associated with car and city bus travel are calculated as shown in Eth. A rate ratio is also calculated to compare the total injury rates associated with car and city bus travel, where total refers to the injury rate for all road users. The rate ratio comparing the total injury rate therefore compares car occupants, Overall, there were 4 times more passenger-kilometers well as pedestrian and cyclist injuries associated with car. car and bus travel are also calculated.

with city busses is insufficient at the route level.

An additional step was carried out to estimate the safety benefits of current (2008) bus travel for each route. The benefit is defined as the number of vehicle occupant, cyclist, and pedestrian injuries saved per passenger-kilometer traveled by bus. This is measured by applying the injury rates estimated for passengerkilometers traveled by car to the observed passengerkilometers by bus. The number of injuries saved is then obtained by subtracting the number of injuries that were previously associated with bus travel from the computed injuries associated with the additional car travel. We also illustrate the association between the numbers of injuries saved as a function of the modal share of bus travel (bus bus, rate ratios are calculated. The rate ratio between car passenger-kilometers/sum of bus and car passenger-

car and bus travel on specific urban roads. The resultsgeometry on car occupant, pedestrian, and cyclist reveal that, per kilometer traveled, bus travel is not only injuries has been extensively studied in the literature safer for vehicle occupants but also for pedestrians and 16, 27–30], while very few studies have linked gecyclists traveling along these ten routes, although thereometry to bus occupant injury occurrences [A is great variation across the routes.

Previous studies aggregated bus travel and injurythe implementation of bus preferential measures, for data for whole regions or countries. This study pro- example, a BRT (bus rapid transit), which was found vides injury rates per passenger-kilometer traveled byto decrease injuries along some corridors but increase bus for each specific route. In Montreal, the routes injuries along others and introduce new safety probwith high injury rates associated with bus travel also lems [31]. The design of public transit and general have high injury rates associated with car travel (Fig. traffic lanes may both affect safety along transit cor-3). This suggests that the same environmental factors [20]. Disaggregate analyses at the route level (e.g., number of lanes, vehicle speed, and density of are necessary to determine the effect of road geomeintersections) may be involved. The effect of road try on injuries for all transportation modes.

By shifting all travel by bus to car, we estimated into account the daily, monthly, or annual variation in the current safety benefits of bus travel along eachpassenger-kilometers nor its evolution over the 10-year of the ten routes. Overall, bus travel saved 1805 study period. We have no other data at the route level vehicle occupants, 156 cyclists, and 476 pedestrians with which to validate our exposure data. An overon ten urban bus routes (over 10 years). The abso-estimation of bus travel or an under-estimation of car lute number of injuries saved by bus travel on each travel would partially explain the observed results, but route varies with the amount of bus travel and with this study is likely over-estimating the car passengerthe difference in injury rates associated with car and kilometers. For car travel, all types of vehicles were bus travel. Our results show kilometers traveled by considered by the vehicle counteven heavy trucks bus result in much fewer injured pedestrians than and busses while only injuries associated with vehikilometers traveled by car. However, it is worth cles under 3000 kg were included. Regardless of these mentioning that in Canada large metropolitan limitations, the injury rate ratio we found for car versus areas, transit access points are concentrated at intebus occupants is quite similar to the non-fatal injury rate sections of wide major roads with the greatest rate of ratio reported for the entire USA by Beck et al. [crashes 19 and pedestrian injuries 2. This reality To explore the variation in pedestrian and cyclist risk also exists in cities like New York, where large of injury (per pedestrian and per cyclist) across specific arterials carry high volumes of car and bus traffic, routes, estimates of pedestrian and cyclist activity would at higher speeds than other streets and where pedesbe required. Furthermore, road typology as well as trian activity is greater 3[3]. Transit system main geometric design and built environment is likely to vary access points are often on busy arterials where pethroughout the route and therefore the injury rate is also destrians already have an elevated risk of injury likely to vary along the route. Future research will take compared to other modes, and with the improvement into account the influence of geometric design of roads of public transit, more pedestrians are to be expected and include injuries associated with the walking portion [20]. To reduce pedestrian injuries, a large reduction of public transit trips. in car volume, area-wide implementation of trafficcalming measures, and safer pedestrian crossings are

needed. Conclusion This study addressed some of the main shortcomings

in the current literature. We only considered city busses This study shows that city bus is a safer mode than car, and estimated car and bus passenger-kilometers along by vehicle occupants but also for pedestrians and cythe ten chosen routes. To compare injury rates betwee clists traveling along these bus routes. Although bus bus and car travel, each route served as its own control travel is safer on all specific routes, there is great varitherefore controlling, to some degree, for roadway enation in the safety benefits at the route level. The varivironment, pedestrian, and cyclist volumes. No previous ation in injury rates and safety benefits of public transit studies have compared the rate of injury for car and bus likely caused by road geometry and other environoccupants at such a disaggregate level. Also, no studies mental factors; disaggregate analyses at the route level have considered the rate of cyclist and pedestrian injurare necessary to determine their effects. The results at ries associated with car and bus travel. One of the main the route level will provide vital information for cities to obstacles to studying bus occupant injury occurrence is properly orient the implementation of environmental obtaining bus occupant exposure, in other words, know-changes as preventative strategies to reduce the risk of ing the number of people riding the bus along all seg-injury for all road users.

Mental transit and cythous independent and cythous injury occurrence is properly orient the implementation of environmental obtaining bus occupant exposure, in other words, know-changes as preventative strategies to reduce the risk of ing the number of people riding the bus along all seg-injury for all road users.

Mental transit and cythous independent and cythous injury occurrence. In the route level will provide vital information for cities to obstacles to studying bus occupant exposure, in other words, know-changes as preventative strategies to reduce the risk of ingure and control transition in the safety benefit

ing along the ten routes.

Support from the Montreal Department of Public Health and the Both car and bus injuries came from the same dataSociété de Transport de Montréal. We would like to express our source, but passenger-kilometers were estimated ratitude to the Société dessurance automobile du Québec through different data sources. The passenger-(SAAQ) for providing the injury data. We would like to thank Céline Plante and Sophie Goudreau from the Montreal Depart-kilometers are based on vehicle and bus occupant count finent of Public Health for their input with the spatial and statistical collected over one single day. This study did not take analysis.
