Aggregate Power Control of Heterogeneous TCL Populations Governed by Fokker–Planck Equations

Jun Zheng, Gabriel Laparra, Guchuan Zhu, Senior Member, IEEE, and Meng Li

Abstract—This article addresses the modeling and control of heterogeneous populations of thermostatically controlled loads (TCLs) operated by model predictive control (MPC) schemes at the level of each TCL. It is shown that the dynamics of such TCLs populations can be described by a pair of Fokker–Planck equations coupled via the actions in the domain. The technique of input–output feedback linearization is used in the design of aggregate power control, which leads to a nonlinear system in a closed loop. Well-posedness analysis is carried out to validate the developed control scheme. The closed-loop stability of the system is assessed by rigorous analysis. A simulation study is contacted, and the obtained results confirm the validity and effectiveness of the proposed approach.

Index Terms—Aggregate load control, Fokker–Planck equation, stability, thermostatically controlled loads (TCLs), well posedness.

I. INTRODUCTION

AGGREGATES of large populations of thermostatically controlled loads (TCLs) can be managed to offer auxiliary services, such as frequency control, load following, and energy balancing, which can contribute to maintaining the overall stability of power networks [1]–[4]. TCLs can also provide a means for absorbing the fluctuations of renewable energy generated by wind turbines and solar photovoltaic plants [1], [5]. Moreover, due to the fact that most of the TCLs, including space heaters, air conditioners, hot water tanks, and refrigerators, exhibit flexibilities in power demand for their operation and elasticities in terms of performance restrictions, they are considered to be one of the most important demand response (DR) resources that can provide such features as power peak shaving and valley filling and enable dynamic pricing schemes in the context of the smart grid [6]–[17].

Indeed, control of aggregated TCL populations is a long-time standing problem, which continues to attract much attention in the recent literature [3], [18]–[20].

The aim of this article is to develop strategies for aggregate power control of heterogeneous TCL populations based on continuum models described by partial differential equations (PDEs). The PDE aggregate model of TCL populations was originally introduced in [21]. Under the assumption of homogenous TCL populations with all the TCLs modeled by thermostat-controlled scalar stochastic differential equations, the dynamics of a population are expressed by two coupled Fokker–Planck equations describing the evolution of the distribution of the TCLs in on and off states, respectively, over a range of temperature. In about a quarter-century later, this PDE aggregate model has been elaborated in [1] to incorporate control actions to manipulate the aggregate of TCL populations, such as the total power consumption. This approach is adopted later by [6], [14], [15], and [22] for different DR applications. A more generic stochastic hybrid system model applicable to a wider class of responsive loads is developed in [23]. PDE aggregate models can also be derived in the framework of deterministic systems. Inspired by the concept of fluid-flow dynamics, a semilinear transport PDE has been derived in [24] for homogeneous TCL populations. It is proposed later in [25] that this PDE model can be extended to describe heterogeneous TCL populations by adding a diffusive term, which indeed results in the same type of PDEs as the one developed in the framework of stochastic systems, i.e., a pair of coupled Fokker–Planck equations. Moreover, a heterogenous population with high diversity can be divided into a finite number of subsets, each of which represents a population with limited variation in its heterogeneity [26].

Another widely adopted model for describing the dynamics of TCL populations is the one originally proposed in [27]. In this model, a temperature deadband is divided into a finite number of segments, called state bins, and the evolution of the distribution of TCLs over the temperature under deadband control is presented by a linear system for which the state transactions can be derived based on Markov chains. This model has been further extended to TCLs of more generic dynamics, e.g., higher order systems, with different control mechanisms for different applications [2]–[4], [17], [28], [29].

In this article, we consider the TCL populations for which the individual TCLs are operated under model predictive control (MPC), which is one of the most frequently adopted techniques in practice due to its ability to handle constraints,
time-varying processes, delays, uncertainties, and disturbances. It should be noted that as with MPC schemes, TCL switching may occur arbitrarily overtime at any point inside a range of temperatures. Consequently, the state-bin model based on the transaction of Markov chains is not applicable. For this reason and being inspired by the work reported in the recent literature, we concentrate on PDE-based aggregate modeling and control of large TCL populations in this article.

The approach adopted in most of the work on PDE-based aggregate power control of TCL populations is based on the technique of early lumping with which the control design is carried out on first discretizing the PDE models over the space [1], [15], [24], [26], [30]. There are a few exceptions, such as the control scheme for output regulation of TCL space [1], [15], [24], [26], [30]. One of the main advantages of this approach is that it can preserve the basic property of the original system, in particular, the closed-loop stability, when the designed control is applied [32].

The control design presented in this article adopts the approach of late-lumping, in which the original PDE model is used. Specifically, the technique of input–output linearization (see [33]–[35]), which is an extension of the same technique for finite-dimensional nonlinear system control [36]–[39], is used in the design of aggregate power (the output) regulation of a TCL population governed by a pair of coupled Fokker–Planck equations. It should be pointed out that this method is greatly inspired by the work presented in [35] while being different in that the control design is carried out directly with the original Fokker–Planck equations. Consequently, a guarantee of closed-loop stability is of primary importance from both theoretical and practical perspectives. To assess the validity of the developed control scheme, an analysis of the well posedness and the stability of the closed-loop system with nonlinear nonlocal terms is performed. It is worth noting that, to the best of our knowledge, the result obtained in this article is novel for PDE-based aggregate power control of large TCL populations. In particular, the results on the well posedness and the stability of Fokker–Planck equations having nonlinear nonlocal terms distributed both in the domain and on the boundary and involving integration in the denominator of nonlocal terms are novel.

The main contributions of this article include:

1) incorporating MPC-based control schemes at the TCL level into an aggregate model of large TCL populations described by a pair of coupled Fokker–Planck equations;
2) developing an aggregated power control scheme based on the technique of input–output linearization for PDE systems;
3) assessing the well posedness of the solutions of the closed-loop system with nonlinear nonlocal terms by the technique of iteration and the generalization of the approach developed in [40];
4) conducting a rigorous stability analysis of the closed-loop system composed of finite-dimensional input–output dynamics and infinite-dimensional internal dynamics.

In the rest of this article, Section II presents the dynamical model of individual TCLs under MPC and the derivation of the aggregate model of homogeneous and heterogeneous TCLs populations. Control design is given in Section III. Wellposedness assessment by the technique of iteration and stability analysis are detailed in Sections IV and V, respectively. A simulation study to evaluate the behavior of the closed-loop system with the developed control scheme is presented in Section VI. Some concluding remarks are provided in Section VII. Finally, details on some technical development are presented in the appendixes.

Notations: If there is no ambiguity, we use the notations $(e^m u/dx^m), D^m_w u, u \times \cdots \times u, u^{(m)}$ to denote the $m$th-order derivative (or weak derivative) of a function $u$ w.r.t. its argument $x$, where $m$ is a nonnegative integer.

For $T \in (0, +\infty)$, let $Q_T = (x, T) \times [0, T)$ with $\overline{Q}_T = [x, T] \times [0, T]$. Denote $Q_{\infty} = (x, T) \times (0, +\infty)$ and $\overline{Q}_{\infty} = [x, T] \times (0, +\infty)$. Let $l$ be a nonintegral positive number. The spaces $H^l([x, T])$ with the norm $\|\cdot\|^{(l)}_{H^l}$ and $H^{l, (l_2)}(Q_T)$ with the norm $\|\cdot\|^{(l_1, l_2)}_{H^{l_1, l_2}}$ are defined in Appendix A.

For $T \in (0, +\infty)$, the space $L^\infty((0, T); L^\infty([x, T]))$ consists of all strongly measurable functions $u : (0, T) \to L^\infty([x, T])$ with the norm

$$
\|u\|_{L^\infty((0, T); L^\infty([x, T]))} = \sup_{0 < s < T} \|u(s)\|_{L^\infty([x, T])}.
$$

Finally, for simplicity, we denote by $\|u\|_p$ the norm $\|u\|_{L^p([x, T])}$ for a function $u \in L^p([x, T])$, where $1 \leq p \leq +\infty$. In particular, we use $\|u\|_2$ to denote $\|u\|_2$.

II. MODELING AGGREGATE OF TCL POPULATIONS

A. Dynamics and Control of Individual TCLs

We consider a large population of thermostatically controlled loads (TCLs) operated in ON/OFF mode. Denote by $x_i$ the temperature of the $i$th load in a population of size $N$. The dynamics of $x_i$ are described by a first-order ordinary differential equation (ODE)

$$
\frac{dx_i}{dt} = \frac{1}{R_i C_i} (x_{ie} - x_i + s_i u_i R_i P_i), \quad i = 1, \ldots, N
$$

(1)

where $x_{ie}$ is the external temperature, $R_i$ is thermal resistance, $C_i$ is thermal capacitance, $P_i$ is thermal power, and $s_i$ is defined as

$$
s_i = \begin{cases} 1, & \text{heating system} \\ -1, & \text{cooling system} \end{cases}
$$

and the switching signal $u_i$:

$$
u_i = \begin{cases} 1, & \text{ON} \\ 0, & \text{OFF} \end{cases}
$$

is generated by an MPC scheme specified below. Note that this hybrid dynamic model is widely adopted in the literature, while deadband-based switching is
the most used control scheme in different works (see [1], [5], [6], [14], [15], [24]–[26]).

The model used in MPC design is a discrete-time system that can be derived from (1) by using the standard scheme of zero-order hold in a sampling period $T_s$, which takes the form

$$x_i(k+1) = A_i x_i(k) + B_i u_i(k) + E_i x_{ie}(k)$$

where the parameters are given by $A_i = e^{-(1/R_iC_i/T_s)}$, $B_i = s_i(P_i/C_i)\int_0^{T_s} e^{-(1/R_iC_i)\tau} d\tau$, and $E_i = (1/R_iC_i)\int_0^{T_s} e^{-(1/R_iC_i)\tau} d\tau$.

Let $x_{ref}$ be the reference signal. Denote by $e_i(k) = x_i(k) - x_{ref}(k)$ the tracking error. Then, to ensure regulation of the problem corresponding to the $i$th subsystem, the MPC design is an optimization problem expressed by [41]

$$\min_{u_i(1),...,u_i(M)} \sum_{k=1}^{M} (e_i(k))_w^2 + (u_i(k))_{R_{mpc}}^2$$

s.t.: $x_i(k+1) = A_i x_i(k) + B_i u_i(k) + E_i x_{ie}(k)$

$x_i(t) \to x_i(0), u_i(t) \to u_i(0), t > 0$

$u_i(k) \in [0, 1]$ $x_{ref}(k) - \Delta x \leq x_i(k) \leq x_{ref}(k) + \Delta x$

where $M$ is the prediction horizon, $Q_{mpc}$ and $R_{mpc}$ are, respectively, the weighting factors applied to penalize the tracking errors and the control efforts, and $\Delta x$ and $\Delta x$ are, respectively, the lower and upper temperature bounds. Switching sequences are determined by the solution of the above-mentioned problem. At each time step of running, the controller computes the solutions until $P$ steps, while only the first one is applied. This process is repeated at the next sampling time, constituting a moving horizon scheme. Note that in the implementation of MPC, the control sequence is applied to the continuous-time system (1) through a mechanism of zero-order hold. Consequently, the hybrid nature of TCLs with their dynamics governed by ODEs while switching between ON and OFF states will be preserved.

B. PDE Model for Heterogeneous Populations of TCLs

Let $v(x, t)$ and $w(x, t)$ be the distribution of loads (number of loads/$^\circ$C) at temperature $x$ and time $t$, over the OFF and ON states, respectively. For notational simplicity, we consider hereafter only the setting for cooling systems. The models for the setting of heating systems can be established in the same way.

First, consider the distribution of loads over the ON state. Let $F(x, t)$ denote the flow of loads at the point $(x, t)$. Then, based on the model describing the microscopic dynamics of individual TCLs given in Section II-A, we have for a population of homogeneous loads

$$F(x, t) = a_1(x) w(x, t)$$

where

$$a_1(x) = \frac{1}{R C} (x_e - x - R P \times 1)$$

with $x_e$, $R$, $C$, and $P$ representing the external temperature, thermal resistance, capacitance, and power, respectively, of the population.

Let $\delta_{0\to1}(x, t)$ denote the added flow due to the switch of loads from OFF state to ON state at $(x, t)$, which is induced by the operation of MPCs at the TCL level. Note that as pointed out in [25], the aggregate power consumption of a heterogeneous TCL population exhibits a damped response to step set-point changes. This property can be represented by the diffusivity added to the macroscopic fluid-flow TCL population model (see [24]), which leads to the following Fokker-Planck equation:

$$\frac{\partial w}{\partial t}(x, t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial w}{\partial x}(x, t) - a_1(x) w(x, t) \right) - \delta_{0\to1}(x, t) \in Q_\infty$$

where $\beta$ is the diffusion coefficient.

Similarly, we can derive the dynamic model of the distribution of loads over the OFF state, which is given by

$$\frac{\partial v}{\partial t}(x, t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial v}{\partial x}(x, t) - a_0(x) v(x, t) \right) - \delta_{1\to0}(x, t) \in Q_\infty$$

where

$$a_0(x) = \frac{1}{RC} (x_e - x)$$

and $\delta_{1\to0}(x, t)$ denotes the added flow due to the switch of loads from ON-state to OFF-state at $(x, t)$.

Suppose that in the considered problem the operation is massconservative, which is the size of the population is constant. Indeed, it is reasonable to assume that no TCLs switches to state 0 from state 1. Then, the flow due to the switch of loads from state 0 to state 1 must verify the compatibility condition $\delta_{0\to1}(x, t) = -\delta_{1\to0}(x, t)$. Therefore, the dynamics of the evolution of the distribution of loads can be expressed by the following coupled Fokker-Planck equations:

$$\frac{\partial w}{\partial t}(x, t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial w}{\partial x}(x, t) - a_1(x) w(x, t) \right) + \delta_{0\to1}(x, t), (x, t) \in Q_\infty$$

$$\frac{\partial v}{\partial t}(x, t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial v}{\partial x}(x, t) - a_0(x) v(x, t) \right) - \delta_{1\to0}(x, t), (x, t) \in Q_\infty$$

To assure the validity of the PDE aggregate model given in (9), we impose the following boundary and initial conditions:

$$\beta \frac{\partial w}{\partial x}(x, t) - a_1(x) w(x, t) = 0$$

$$\beta \frac{\partial v}{\partial x}(x, t) - a_0(x) v(x, t) = 0$$

$$\beta \frac{\partial v}{\partial x}(x, 0) - a_0(x) v(x, 0) = 0$$

which guarantees the conservativity of mass of the problem under consideration, as stated in the following.
Proposition 1: Let the size of the population modeled by (9) and (10) be defined as

\[ N_{\text{agg}}(t) = \int_{\Delta} (w(x,t) + v(x,t))dx, \quad t \geq 0. \]

We have then

\[ N_{\text{agg}}(t) = N_{\text{agg}}(0) = \int_{\Delta} (w^0(x) + v^0(x))dx \quad \forall t \geq 0. \]

Proof: The result can be obtained directly by taking integration of (9) and using the boundary conditions (10). ■

Remark 1: In the formulation proposed in this article, the reference temperature is the same for all the TCLs in the population. However, it is important to note that the range of the turn-on and turn-off temperatures can be different from other TCLs depending on its performance requirement and power consumption consideration. This feature is significantly different from that in thermostat-based deadband control schemes where the turn-on and turn-off temperatures are identical for all the TCLs in the same population.

For notational simplicity, we may ignore hereafter the domain on which the system is defined and the arguments of different functions if there is no ambiguity.

C. Controlled PDE Model for Power Consumption Control

As mentioned earlier, power consumption control of a TCL population can be achieved by moving the control volume with the set-point temperature [1], [24], [26]. By taking the time-derivative of the set-point as the control input \( u(t) = \delta_{\text{ref}} \), the dynamics of the evolution of the distribution of a population of heterogenous loads can be expressed by the following forced Fokker–Planck equations:

\[
\frac{\partial w}{\partial t}(x,t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial w}{\partial x}(x,t) - (a_1(x) - u(t))w(x,t) \right) + \delta(x,t), \quad (x,t) \in Q_{\infty} \tag{11a}
\]

\[
\frac{\partial v}{\partial t}(x,t) = \frac{\partial}{\partial x} \left( \beta \frac{\partial v}{\partial x}(x,t) - (a_0(x) - u(t))v(x,t) \right) - \delta(x,t), \quad (x,t) \in Q_{\infty} \tag{11b}
\]

with the following boundary and initial conditions:

\[
\beta \frac{\partial w}{\partial x}(x,t) - (a_1(x) - u(t))w(x,t) = 0 \tag{12a}
\]

\[
\beta \frac{\partial v}{\partial x}(x,t) - (a_1(\bar{x}) - u(t))w(\bar{x},t) = 0 \tag{12b}
\]

\[
\beta \frac{\partial v}{\partial x}(x,t) - (a_0(x) - u(t))v(x,t) = 0 \tag{12c}
\]

\[
\beta \frac{\partial w}{\partial x}(x,t) - (a_0(\bar{x}) - u(t))v(\bar{x},t) = 0 \tag{12d}
\]

\[
w(x,0) = w^0, \quad v(x,0) = v^0. \tag{12e}
\]

For the validity of the PDE aggregate model given in (11) and (12), it is expected that the closed-loop system preserves the property of mass conservativity, which is guaranteed by Proposition 2 given later in Section IV.

III. CONTROL DESIGN

For the purpose of controlling the power consumption of the whole population of TCLs, we take the weighted total power consumption as the system output

\[ y(t) = \frac{P}{\eta} \int_{\Delta} (ax + b)w(x,t)dx \tag{13} \]

where \( a \) and \( b \) are constants with \( a \neq 0 \). The purpose of introducing the weighting function \( ax + b \) in system output defined earlier is to guarantee that the input–output dynamics of the system are well defined in terms of the characteristic index that is an analog of the concept of relative degree for finite-dimensional systems [33], [34]. The reason to use a specific weighting function in (13) is mainly due to the fact that, in general, it is very difficult, if not impossible, to conduct well posedness and stability analysis for nonlinear PDEs with generic nonlinear terms. Note that the weighting function is not unique and it can be chosen and tuned in control design and implementation depending on control objectives and performance requirements.

We consider in this article a set-point control problem where the objective is to drive the power consumption of the whole population to the desired level \( y_d \) representing the demand from, e.g., energy suppliers.

Denoting by \( e(t) = y(t) - y_d \) the regulation error, we can derive from (11a) and (13) that

\[
\frac{de}{dt} = \frac{P}{\eta} \int_{\Delta} (ax + b) \frac{\partial w}{\partial t} dx
\]

\[
= \frac{P}{\eta} \int_{\Delta} (ax + b) \left( \beta \frac{\partial w}{\partial x} - (a_1(x) - u(t))w \right) dx
\]

\[
+ \frac{P}{\eta} \int_{\Delta} (ax + b)\delta(x,t) dx.
\]

Performing integration by parts and applying the boundary conditions (12), we get

\[
\frac{de}{dt} = -\frac{P}{\eta} \int_{\Delta} a \left( \beta \frac{\partial w}{\partial x} - (a_1(x) - u(t))w \right) dx
\]

\[
+ \frac{P}{\eta} \int_{\Delta} (ax + b)\delta(x,t) dx.
\]

Let

\[
\Gamma(t) = \frac{P}{\eta} \int_{\Delta} (ax + b)\delta(x,t) dx. \tag{15}
\]

Then, the regulation error dynamics becomes

\[
\frac{de}{dt} = \phi(t) + \Gamma(t), \quad e(0) = e_0 \tag{16}
\]
where \( \phi(t) \) is an auxiliary control, and \( e_0 \) is the initial regulation error.

**Remark 2:** It can be seen from (14) that the characteristic index of the input–output dynamics of the system is \( 1 \) if at any time the power consumption of the whole population is not null. This constraint is a natural property for a TCL population of sufficiently large size and can be guaranteed by a simple operation in practice.

**Remark 3:** Note that the term \( \Gamma(t) \) represents the effect of switching induced by the MPCs at the TCL level. An advantage of treating \( \Gamma(t) \) as a disturbance in the proposed aggregate power control scheme is that the TCLs do not need to signal the instantaneous switching operations, which will allow greatly simplifying the implementation and considerably relaxing the performance requirement on communication systems. Moreover, the developed control algorithm is a partial state-feedback scheme depending only on \( w(x,t) \), which is exactly the same information needed for computing the system output [1], [15], [24], [26], [30], [31]. Finally, communicating nonlinear nonlocal terms, which brings the following two obstacles for well-posedness analysis.

1. Due to the appearance of a nonlinear nonlocal term in the form of \( w(x,t) \int a_1(x)w(x,t)\,dx/\int w(x,t)\,dx \), one cannot deal with the original PDEs directly and apply the Lyapunov method to obtain the a priori estimates of the solutions. Consequently, the Galerkin method cannot be directly used for well-posedness analysis.
2. The corresponding PDEs may have a singularity due to the appearance of the term \( \int w(x,t)\,dx \) in the denominator of the nonlocal term. Therefore, the classical Leray–Schauder fixed-point theorem cannot be applied directly in well-posedness analysis.

To overcome the difficulties brought by the nonlinear nonlocal character, we use in this article the technique of iteration for well-posedness analysis.

**Theorem 1:** Consider the closed-loop system. For any \( T > 0 \), there exists \( (w, v) \in H^{2+\theta,1+\theta/2}(Q_T) \times H^{2+\theta,1+\theta/2}(Q_T) \) that satisfies (11) a.e. in \( Q_T \).

It should be pointed out that with the proposed control scheme, the closed-loop system is governed by parabolic PDEs with nonlinear nonlocal terms, which brings the following two obstacles for well-posedness analysis.

1. To overcome the difficulties brought by the nonlinear nonlocal character, we use in this article the technique of iteration for well-posedness analysis.

**IV. WELL POSEDNESS OF THE CLOSED-LOOP SYSTEM**

In this section, we establish the well posedness of the closed-loop system composed of (11)–(17). To this aim, we note that \( a_1, a_0 \in C^1([\underline{\xi}, \overline{\xi}]) \) and \( P, \beta, \) and \( \eta \) are positive constants, and assume that

\[
\begin{align*}
&\omega^0, v^0 \in H^{2+\theta}([\underline{\xi}, \overline{\xi}]), \quad \delta \in L^\infty((0, \infty) \cap L^\infty(\underline{\xi}, \overline{\xi})) \quad (18)
\end{align*}
\]

with

\[
\begin{align*}
&\int_\Delta w^0(x)dx + \int_0^\tau \int_\Delta \delta(x,s)dxds \geq \delta_0 > 0 \quad \forall \tau \in (0, +\infty)
\end{align*}
\]

where \( \theta \in (0, 1) \), \( \delta_0 > 0 \) are constants. Note that the conditions given in (19a) and (19b) mean that at any time the TCLs are not all in off-state.
5) for any $n \geq 1$ and $t \in [0, T]$, it holds

$$\int_{\Omega} w^0(x) dx + \int_0^t \int_{\Omega} \delta_n(x, s) ds ds \geq \frac{\delta_0}{2} > 0. \quad (20)$$

Consider the following two sets of iterating equations in $Q_T$:

$$\begin{align*}
\frac{\partial w_n}{\partial t}(x, t) &= -\frac{\partial}{\partial x} \left( a_1(x) w_n(x, t) \right) + \beta \frac{\partial^2 w_n}{\partial x^2}(x, t) \\
&\quad - \frac{\partial w_n}{\partial x}(x, t) G_{w_n-1}(t) + \delta_n(x, t) \quad (21a) \\
\beta \frac{\partial w_n}{\partial x}(x, t) - a_1(x) w_n(x, t) - w_n(x, t) G_{w_n-1}(t) &= 0 \quad (21b) \\
\frac{\partial v_n}{\partial t}(x, t) &= -\frac{\partial}{\partial x} \left( a_1(x) v_n(x, t) \right) + \beta \frac{\partial^2 v_n}{\partial x^2}(x, t) \\
&\quad - \frac{\partial v_n}{\partial x}(x, t) G_{v_n}(t) + \delta_n(x, t) \quad (22a) \\
\beta \frac{\partial v_n}{\partial x}(x, t) - a_0(x) v_n(x, t) - v_n(x, t) G_{v_n}(t) &= 0 \quad (22b) \\
v_n(x, 0) = v^0(x) \quad (22d)
\end{align*}$$

where

$$G_{w_n-1}(t) = \int_{\Omega} \left( \beta \frac{\partial w_n-1}{\partial x} - a_1 w_n-1 \right) dx$$

$$- k_0 \int_{\Omega} (ax + b) w_n-1 dx - \frac{\theta}{\alpha} y_d, \quad n \geq 1$$

with $w_0(x, t) := w^0(x)$.

We claim that for any $n$, there exists a unique solution $w_n, v_n \in H^{2,0,1+\theta/2}(Q_T)$ to the iterating (21) and (22), respectively.

**Lemma 1:** For any $n$, (21) and (22) admit a unique solution $w_n \in H^{2,0,1+\theta/2}(Q_T)$ and $v_n \in H^{2,0,1+\theta/2}(Q_T)$ respectively, satisfying for any $t \in [0, T]$:

$$\int_{\Omega} w_n(x, t) dx = \int_{\Omega} w^0(x) dx + \int_0^t \int_{\Omega} \delta_n(x, s) ds ds \geq \frac{\delta_0}{2}$$

$$\int_{\Omega} v_n(x, t) dx = \int_{\Omega} v^0(x) dx - \int_0^t \int_{\Omega} \delta_n(x, s) ds ds \geq \frac{\delta_0}{2}$$

and

$$\|w_n(\cdot, t)\|_1 \leq \|w^0\|_1 + \int_0^t \int_{\Omega} \delta_n(x, s) \text{sgn}(w_n) dx ds \quad (23a)$$

$$\|v_n(\cdot, t)\|_1 \leq \|v^0\|_1 - \int_0^t \int_{\Omega} \delta_n(x, s) \text{sgn}(v_n) dx ds. \quad (23b)$$

Moreover, $(w_n$ and $v_n$) has the following uniform estimates:

$$\max_{Q_T} |w_n| + \max_{Q_T} |w_n| + |w_n|^{(2+\theta)} \leq C_1 \quad (24a)$$

$$\max_{Q_T} |v_n| + \max_{Q_T} |v_n| + |v_n|^{(2+\theta)} \leq C_2 \quad (24b)$$

where $C_1$ and $C_2$ are positive constants independent of $n$.

**Proof:** The proof is proceeded in four steps as detailed in Appendix B.

**Remark 4:** The main mathematical framework used in the proof of Lemma 1 is as follows.

1) The existence of a unique solution $(w_n, v_n) \in H^{2,0,1+\theta/2}(Q_T) \times H^{2,0,1+\theta/2}(Q_T)$ is proven by induction combining with the well posedness and regularity theory for quasilinear parabolic equations in [40, Ch. V].

2) The $L^1$-estimates of $w_n$ and $v_n$ in (23) are established by utilizing appropriate test functions and some basic integrating techniques. Note that since $\|\delta_n \text{sgn}(w_n)\|_\infty \leq 1 + \|\delta\|_\infty$ and $\|\delta_n \text{sgn}(v_n)\|_\infty \leq 1 + \|\delta\|_\infty$, (23) implies the uniform boundedness of $\|w_n\|_1$ and $\|v_n\|_1$, respectively.

3) The uniform boundedness of $\|w_n\|_1$ and $\|v_n\|_1$ and the continuity of $w_n$ and $v_n$ guarantee the uniform boundedness of $w_n$ and $v_n$, which, along with the well posedness and regularity theory for quasilinear parabolic equations in [40, Ch. V], guarantees the uniform estimates of $w_n$ and $v_n$ in (24).

Based on Lemma 1, we can establish the existence and the regularity of a solution $(w, v)$ to the coupled (11) in closed loop formed by (11)–(17).

**Proof:** **Proof of Theorem 1:** By Lemma 1, $(w_n, v_n)$ is bounded in $H^{2,0,1+\theta/2}(Q_T) \times H^{2,0,1+\theta/2}(Q_T)$. Then, by choosing a subsequence, there is a pair of functions $(w, v) \in H^{2,0,1+\theta/2}(Q_T) \times H^{2,0,1+\theta/2}(Q_T)$ satisfying $(w_n, v_n) \to (w, v)$ in $H^{2,0,1+\theta/2}(Q_T) \times H^{2,0,1+\theta/2}(Q_T)$ as $n \to \infty$. Noting that $\delta_n \to \delta$ a.e. in $Q_T$, we conclude that $(w, v)$ satisfies (11) a.e. in $Q_T$.

It should be noticed that Theorem 1 can still guarantee the uniqueness of a solution of the closed-loop system, because the solution is obtained by the technique of iteration and approximation. Moreover, in general it is not trivial to establish the uniqueness of a solution to an equation with strong nonlinearities. Nevertheless, the uniqueness of the solution of the closed-loop system can be guaranteed in a weak sense as stated in the following.

**Theorem 2:** Consider the closed-loop system. Let $(w_1, v_1), (w_2, v_2) \in H^{2,0,1+\theta/2}(Q_T) \times H^{2,0,1+\theta/2}(Q_T)$ be two solutions of (11) in $Q_T$. If $w_1(\overline{x}, t) - \overline{w_1}(\overline{x}, t) = w_2(\overline{x}, t) - \overline{w_2}(\overline{x}, t)$ in $[0, T]$, then $(w_1, v_1) = (w_2, v_2)$ in $Q_T$.

**Proof:** See Appendix C.

**V. STABILITY ANALYSIS**

We assess first the stability of the error dynamics (16) with the control given in (17).
Theorem 3: The regulation error $e(t)$ is determined by

$$e(t) = e(0)e^{-kt} + \int_0^t \Gamma(t)e^{-k(t-s)}ds. \quad (25)$$

Furthermore, if $|\Gamma(t)| \leq \Gamma_{\infty}$ with a positive constant $\Gamma_{\infty}$ for all $t > 0$, then

$$|e(t)| \leq |e(0)|e^{-kt} + \frac{\Gamma_{\infty}}{k_0}(1 - e^{-kt}) \quad \forall t > 0.$$ 

Proof: By (16) and (17), it follows:

$$\frac{de}{dt} = -k_0e(t) + \Gamma(t), \quad e(0) = e_0.$$ 

Solving this first-order linear ODE, we can obtain the result given in (25).

To assure the closed-loop stability, we need to prove that the internal dynamics composed of (11)-(14) are stable provided Theorem 3 holds true. Toward this aim, we need the properties stated in the following two propositions. The first one is the conservativeness of mass of the considered problem given in the following.

Proposition 2: Consider the closed-loop system. For any $T > 0$, let $(w, v) \in \mathcal{H}^{2+\theta,1+\gamma/2}(Q_T) \times \mathcal{H}^{2+\theta,1+\gamma/2}(Q_T)$ satisfy (11) a.e. in $Q_T$. Then, for any $t \in [0, T]$, it holds the following:

1) \begin{align*}
\int_0^T w(x,t)dx = \int_0^T w^0(x)dx + \int_0^t \int_0^T \delta(x,s)dsdxs.
\end{align*}

2) \begin{align*}
\int_0^T v(x,t)dx = \int_0^T v^0(x)dx - \int_0^t \int_0^T \delta(x,s)dsdxs.
\end{align*}

Moreover, it holds

$$N_{agg}(t) = \int_0^T (w(x,t)+v(x,t))dx = \int_0^T (w^0(x)+v^0(x))dx.$$ 

Proof: The result can be obtained directly by taking integration of (11) and using the boundary conditions (12).

In order to establish the stability of the closed-loop system, we need the following property on the solutions of (11)-(17).

Proposition 3: Consider the closed-loop system. For any $T > 0$, let $(w, v) \in \mathcal{H}^{2+\theta,1+\gamma/2}(Q_T) \times \mathcal{H}^{2+\theta,1+\gamma/2}(Q_T)$ be a solution of (11) in $Q_T$. Then, for any $t \in [0, T]$, the estimates hold the following:

1) \begin{align*}
\|w(\cdot,t)\|_1 \leq \|w^0\|_1 + \int_0^t \int_0^T \delta(x,s)sgn(w)\ ds\ dsdxs.
\end{align*}

2) \begin{align*}
\|v(\cdot,t)\|_1 \leq \|v^0\|_1 - \int_0^t \int_0^T \delta(x,s)sgn(v)\ ds\ dsdxs
\end{align*}

where $sgn(\eta) = 1$ if $\eta > 0$, $sgn(\eta) = -1$ if $\eta < 0$, and $sgn(\eta) = 0$ if $\eta = 0$.

Proof: By Lemma 1 and the regularity of $w_n$ and $v_n$, it suffices to let $n \to \infty$ in (23), which leads to the desired result.

As it is guaranteed by Proposition 2 that the closed-loop system is also conservative in terms of the total number of TCLs in the population, there must be a positive constant $M$ such that $\int_0^T \delta(x,t)dt < M$ for any Lebesgue measurable set $Q \subset Q_{\infty}$. Then, we have the following result regarding the stability of the internal dynamics in closed loop.

Theorem 4: Consider the internal dynamics of the system. Let $(w, v) \in \mathcal{H}^{2+\theta,1+\gamma/2}(Q_\infty) \times \mathcal{H}^{2+\theta,1+\gamma/2}(Q_\infty)$ satisfy (11) a.e. in $Q_{\infty}$. Assume that there exists a positive constant $M$ such that $\int_0^Q \delta(x,t)dt < M$ for any Lebesgue measurable set $Q \subset Q_{\infty}$. Then, for any $t \in [0, +\infty)$, it holds the following:

1) \begin{align*}
\|w(\cdot,t)\|_1 \leq \|w^0\|_1 + 2M < +\infty.
\end{align*}

2) \begin{align*}
\|v(\cdot,t)\|_1 \leq \|v^0\|_1 + 2M < +\infty.
\end{align*}

Proof: We assess only the claim: 1) the proof of the claim and 2) can follow the same line. Indeed, for $t = 0$, we have yet $\|w(0)\|_1 = \|w^0\|_1 \leq \|w^0\|_1 + 2M < +\infty$. For any $t > 0$, let $Q^+ = \{(x,s) \in Q_\infty; w(x,s) > 0\}$ and $Q^- = \{(x,s) \in Q_\infty; and w(x,s) < 0\}$. Then, by assumptions and Proposition 3, we have

$$\|w(\cdot,t)\|_1 \leq \|w^0\|_1 + \int_0^t \int_Q \delta(x,s)sgn(w)\ ds\ dsdxs,$$

which is bounded by $\|w(0)\|_1 + \frac{1}{2} M < +\infty$.

VI. SIMULATION STUDY

To validate the developed control scheme and illustrate the performance of the system, we conduct a simulation study on a benchmark problem, corresponding to a population of air conditioners, which has been used in the validation of different solutions in the literature [1], [25], [31], [42]. The parameters of the system and the controllers are listed in Table I. The variation of thermal capacitance creates a heterogenous TCL population.

The settings used in the simulation is a population of 1000 appliances controlled by MPC schemes. The simulation is performed on a normalized time scale with respect to the nominal time constant of the appliances represented by $RC (= 20)$. The results related to power consumption are also presented in quantities normalized by the maximal total power consumption of the population. Note that taking $b = -20$ in the weighting function used in the output function defined in (13) has the effect of moving the data around the center of the operation range. Our experiment has shown that this choice would facilitate controller tuning.

First, it is known that due to the phenomenon of cold load pickup [43], a step variation of temperature reference in a large population of TCLs may induce high-power demand peaks. To avoid this problem, we have adopted a decentralized desynchronization mechanism that combines adding a weighting coefficient and a delay to the reference signal at the level of MPC for individual TCLs independently [44]. To illustrate the effect of this desynchronized MPC scheme, we tested the response of the population to a step change of the reference from 20.5 °C to 19 °C occurred at $t = 15$. The MPCs are with a weighting coefficient $R_{\text{mpc}}$ from a normally distributed random variable restricted in the interval $[0, 5]$ to the reference signal. It can be seen from Fig. 2 that the desynchronized MPC scheme can considerably reduce the peak power demand.

The second part of the simulation study is to determine the diffusion coefficient, $\beta$, of the Fokker–Planck equations based on the experiments. The diffusivity is estimated by applying the algorithm developed in [42] to the data generated by numerical simulations, which gives a value $\beta = 0.1$. To validate this result, we proceed by first generating the data $\delta(x, t)$ for the population of TCLs specified in Table I with MPC at the TCL level. The numerical solutions of the Fokker–Planck equations with the generated data $\delta(x, t)$ as the inputs corresponding to different values of $\beta$ are obtained by the forward Euler method [45]. The solution surfaces of the Fokker–Planck equations, $w(x, t)$ and $v(x, t)$, with $\beta = 0.1$ are shown in Fig. 3(a). Then, we compute the normalized mean error in its absolute value of the number of the TCLs in ON and OFF states between the generated data and that given by the solution of the Fokker–Planck equations with different diffusion coefficient varying from 0 to 0.2. As can be seen from Fig. 3(b) that $\beta = 0.1$ is an adequate estimate. It can also be observed that the errors are not sensitive to the diffusion coefficient if it is smaller than 0.1. This is in accordance with the results reported in the literature (see [42]).

In the last part of simulation study, we test the developed aggregate power control algorithm with a case where
the desired aggregate power changes from 0.41 to 0.47 at $t = 15$ (all in the normalized scale), which corresponds to a variation of the reference temperature from 20.5 °C to 19 °C [1], [24], [25]. The desired aggregate power and the actual power consumption of the population are shown in Fig. 4(a). The control signal and the regulation errors are shown in Fig. 4(b) and (c), respectively. The results show that the developed control scheme performs well with regulation errors lower than 2.5% of the maximum total power consumption at the steady regime. In order to avoid the chartering induced by fast reference variations, the reference sent to the TCLs is the average of the values over the last ten iterations. The obtained temperature reference is shown in Fig. 5(a). Fig. 5(b) shows the temperature evolution of 100 randomly selected TCLs. It can be seen that all the TCLs follow well the reference while respecting the temperature deadband. Finally, it is worth noting that in the simulation, we used a population containing 1000 TCLs. As the bigger is the size of the population, the more accurate is the continuum model, along with the fact that the switching of the TCLs, is considered unknown as specified in (16), the simulation results confirmed the robustness of the developed control scheme.

VII. CONCLUSION

In this article, we have developed an input–output linearization-based scheme for aggregate power control of heterogenous thermal TCL populations governed by a pair of Fokker–Planck equations coupled via in-domain actions representing the operation of MPC at the level of individual TCLs. Well posedness and stability analysis on the closed-loop system is conducted. A simulation study is carried out with a benchmark set, and the results illustrated the validity and performance of the proposed method.

It should be noted that this article considered only a set-point regulation problem. While as the proposed linearization control leads to a system with finite-dimensional linear input–output dynamics, it is straightforward to extend this scheme to aggregate power tracking by using the well-established techniques for tracking control of finite-dimensional systems [36]–[39]. Finally, the control algorithm developed in this article can be applied to TCL populations operated by other control schemes at the level of individual TCLs, in particular, the variations of deadband control. The main difference will be the way with which the PDEs are coupled, which will lead to settings with different boundary conditions and in-domain inputs. Hence, the well posedness and the stability of the closed-loop systems have to be assessed, which can also be conducted following the approach used in this article.

APPENDIX A
NOTATIONS ON $H^l((\mathcal{X}, \overline{\mathcal{X}}))$ AND $H^{l,1/2}(\mathcal{Q}_T)$

We introduce first the following definitions of function spaces given in [40, Ch. I], which are used in the subsequent development. Let $T > 0$ and $l$ be a nonintegral positive number. $H^l((\mathcal{X}, \overline{\mathcal{X}}))$ denotes the Banach space whose elements are continuous functions $u(x)$ in $[\mathcal{X}, \overline{\mathcal{X}}]$, having continuous derivatives up to order $[l]$ inclusively and a finite value for the quantity

$$\langle u^{(l)} \rangle_{Q_T} = \langle u^{(l)} \rangle_{\mathcal{X}, \overline{\mathcal{X}}} + \sum_{j=0}^{[l]} \langle u^{(j)} \rangle_{\mathcal{X}, \overline{\mathcal{X}}}$$

where (26) defines the norm $\|u^{(l)}\|_{H^l((\mathcal{X}, \overline{\mathcal{X}}))}$.

$H^{l,1/2}(\mathcal{Q}_T)$ denotes the Banach space of functions $u(x,t)$ that are continuous in $\mathcal{Q}_T$, together with all derivatives of the form $D^r D^s x \! \cdot \! D^{r/2} D^{s/2} t$, for $2r + s < l$, and have a finite norm

$$\langle u^{(l)} \rangle_{\mathcal{Q}_T} = \langle u^{(l)} \rangle_{\mathcal{Q}_T} + \sum_{j=0}^{[l]} \langle u^{(j)} \rangle_{\mathcal{Q}_T}$$

with

$$\langle u^{(0)} \rangle_{\mathcal{Q}_T} = \langle u^{(0)} \rangle_{\mathcal{Q}_T} = \max_{\mathcal{Q}_T} |u|$$

$$\langle u^{(j)} \rangle_{\mathcal{Q}_T} = \sum_{(2r + s = j)} \|D^r D^s x \! \cdot \! D^{r/2} D^{s/2} t\|_{\mathcal{Q}_T}$$

$$\langle u^{(l)} \rangle_{\mathcal{Q}_T} = \langle u^{(l)} \rangle_{\mathcal{Q}_T} + \langle u^{(l/2)} \rangle_{\mathcal{Q}_T}$$

$$\langle u^{(l/2)} \rangle_{\mathcal{Q}_T} = \sum_{0 < l - 2s < 2} \|D^r D^s x \! \cdot \! D^{r/2} D^{s/2} t\|_{\mathcal{Q}_T}$$

$$\langle u^{(a)} \rangle_{\mathcal{Q}_T} = \sup_{(x,t),(x',t') \in \mathcal{Q}_T, |t - t'| \leq \rho_0} \|u(x,t) - u(x',t')\|$$

$$\langle u^{(r)} \rangle_{\mathcal{Q}_T} = \sup_{t \in (0,T)} \rho \cdot \text{osc}_{\mathcal{Q}_T} \{u(x,t); \Omega_{\rho}\}$$
In the last line, the second supremum is taken over all connected components \( \Omega'_\rho \) of all \( \Omega_\rho \) with \( \rho \leq \rho_0 \), while \( \text{osc}_x \{u(x,t) ; \Omega'_\rho \} \) is the oscillation of \( u(x,t) \) on \( \Omega'_\rho \), i.e.,

\[
\text{osc}_x \{u(x,t) ; \Omega'_\rho \} = \{ \text{vrai sup}_{x \in \Omega'_\rho} u(x,t) - \text{vrai inf}_{x \in \Omega'_\rho} u(x,t) \}, \quad \rho_0 = \lambda - \delta, \quad \Omega_\rho = K_\rho \cap (x, \lambda), \quad \text{and} \quad K_\rho \text{ is an arbitrary open interval in } (-\infty, +\infty) \text{ of length } 2\rho.
\]

APPENDIX B
PROOF OF LEMMA 1

The proof of Lemma 1 can proceed in four steps.

**Step 1:** We prove the existence of solutions of (21) and (22) by induction combining with the generalization of the approach developed in [40].

**Lemma 2:** For any \( n \), (21) and (22) have a unique solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) and \( v_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \), respectively.

**Proof:** First, we prove the existence and the uniqueness of the solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) of (21). We rewrite (21) as follows:

\[
\frac{\partial w_n}{\partial t}(x,t) - \beta w_{nx,x} + b_n(x,t, w_n, w_{nx}) = 0
\]

and

\[
\beta w_{nx,x}(x,t) + \psi_n(x, t, w_n) = 0
\]

where \( b_n(x,t, w, p) = a_1 (x, w + (a_1 + G_{w_n}(t)) p) - \delta_n(x,t) \) and \( \psi_n(x, t, w) = (\lambda + H - 2x) (a_1 + G_{w_n}(t)) \).

We proceed by induction to show that (28) has a unique solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) which satisfies

\[
\max_{\Omega_T} |w_n| \leq m_n, \quad \max_{\Omega_T} |w_{nx}| \leq M_n, \quad |w_n|_{2+\theta/2} \leq M_n
\]

where \( m_n \) depends only on \( a, b, k_0, \theta, \beta, \mid \alpha \mid \infty, \mid \alpha_1 \mid \infty, \mid \beta \mid \infty, \max_{\Omega_T} |w_{n-1}|, \) and \( \int_\Omega w_0^2 \) and \( n \) and \( M_n \) depend only on \( \beta, \lambda_x, m_n, \mid \alpha_1 \mid \infty, \max_{\Omega_T} |w_{n-1}|, \) and \( \mid \alpha \mid \infty, \mid \beta \mid \infty, \mid \lambda_x \mid \infty, \mid \alpha_1 \mid \infty, \) and \( \mid \beta \mid \infty, \mid \lambda_x \mid \infty, \mid \alpha_1 \mid \infty, \) and \( \mid \beta \mid \infty, \mid \lambda_x \mid \infty, \mid \alpha_1 \mid \infty, \)

Indeed, for \( n = 1 \), recalling that \( a_1(0,0) = C(1, \lambda), \) and \( \int_\Omega w_0^2 \) > 0, there exists a constant \( g_0 \) > 0 depending only on \( a, b, k_0, \theta, \beta, \mid \alpha \mid \infty, \mid \alpha_1 \mid \infty, \mid \beta \mid \infty, \mid \lambda_x \mid \infty, \mid \alpha_1 \mid \infty, \) and \( \int_\Omega w_0^2 \) such that \( |G_{w_n}(t)| \leq g_0 \) for any \( t \geq 0 \). For any \( w \) and \( p \), we have

\[
-wb_1(x, t, w, p) \leq \left( \frac{|\alpha_1|}{2} + \frac{|a_1| + g_0 + 1}{2} \right) p^2 \quad \text{and} \quad |\alpha_1| \leq g_0 + 1 \quad \text{and} \quad |G_{w_n}(t)| \leq g_0 \quad \text{for any} \quad t \geq 0.
\]

Therefore, (28) has a unique solution \( w_1 \in H^{2+\theta,1+\theta/2}(\Omega_T) \). Moreover, by [40, Ch. V, Th. 7.2 and 7.3], we have the following estimates:

\[
\max_{\Omega_T} |w_1| \leq \lambda_1 e^{\lambda_1 \theta/2} \max_{\Omega_T} \left( w_0(x, t) \right) := m_1
\]

\[
\max_{\Omega_T} |w_1| \leq M_1
\]

where \( \lambda_1 \) and \( \delta_1 \) depend only on \( \beta, c_0, \theta_1, c, \) and \( M_1 \) depends only on \( \beta, \lambda_x, m_1, \max_{\Omega_T} |G_{w_1}(t)| \). Furthermore, by [40, Ch. V, Th. 5.4], we have

\[
|w_1(2+\theta/2) \leq M_1
\]

Assuming that for \( n = k \) (28) has a unique solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) satisfying (29), we prove the claim for \( n = k + 1 \), where \( k > 1 \) is an integer. Noting that by (21), for all \( t \in [0, T] \), it follows:

\[
\int_\Omega w_k(x,t)dx = \int_\Omega w_0(x)dx + \int_0^T \int_\Omega \delta_k(x,t)dxdt
\]

By the definition of \( G_{w_k}(t) \), (19b) and (29), it follows:

\[
|G_{w_k}(t)| \leq \gamma_k \quad \forall t \in [0, T]
\]

where \( \gamma_k \) is a positive constant depending only on \( T, \delta_0, a, b, k_0, \theta, \beta, \) and \( |\alpha|, |\alpha_1|, \max_{\Omega_T} |w_k|, \) and \( \int_\Omega w_0^2 \). Then, for any \( w_0 \) and \( p_0 \), we have

\[
-wb_{k+1}(x, t, w, p) \leq c(k+1) + c(k+1)x + (c(k+1) + c(k+1)) w^2 + c(k+1) x
\]

where \( c(k+1), c(k+1), c(k+1), \) and \( c(k+1) \) are positive constants depending only on \( g_k, |\alpha_1| \infty, |\alpha_1| \infty, \) and \( |\beta| \infty, \)

By [40, Ch. V, Ths. 5.4 and 7.2–7.4], we conclude that (28) has a unique solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) for \( n = k + 1 \), having the estimates in (29). Therefore, (21) has a unique solution \( w_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) for every \( n \geq 1 \).

Then, we have that for any \( n \), there exists \( w_n \) satisfying (21). Recalling the definition of \( G_{w_n}(t) \), \( G_{w_n}(t) \) is fixed. Therefore, (22) is a linear equation. Finally, the existence of a unique solution \( v_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) to (22) is guaranteed by [40, Ch. V, Th. 7.4]. Moreover, \( v_n \) has similar estimates as (29), that is,

\[
\max_{\Omega_T} |v_n| + \max_{\Omega_T} |v_{nx}| \leq C_n
\]

with a certain positive constant \( C_n \).

**Step 2:** We prove a property of \( (w_n \) and \( v_n \) in the following.

**Lemma 3:** Let \( w_n, v_n \in H^{2+\theta,1+\theta/2}(\Omega_T) \) be the solutions to (21) and (22), respectively. For any \( n \) and any \( t \in [0, T] \), the following equalities hold:

\[
\int_\Omega w_n(x,t)dx = \int_\Omega w_0(x)dx + \int_0^T \int_\Omega \delta_n(x,s)dxds \geq \frac{\delta_0}{2}
\]

\[
\int_\Omega v_n(x,t)dx = \int_\Omega u_0(x)dx - \int_0^T \int_\Omega \delta_n(x,s)dxds \geq \frac{\delta_0}{2}
\]

**Proof:** It suffices to integrating over \((x, t)\) and using the boundary conditions and (20).
Step 3: We prove the following property of \((w_n, v_n)\) which implies that \((w_n, v_n)\) is uniformly bounded in \(L^1\)-norm.

Lemma 4: Let \(w_n, v_n \in H^{2+\theta, 1+((2\theta)/2)}(Q_T)\) be the solutions to (21) and (22), respectively. For any \(n\) and any \(t \in [0, T]\), the estimates hold the following:

1) \(\|w_n(c, t)\|_1 \leq \|w_0\|_1 + \int_0^t \int_{Q_T} \delta_n(x, s) \text{sgn}(w_n)dxds\).

2) \(\|v_n(c, t)\|_1 \leq \|v_0\|_1 - \int_0^t \int_{Q_T} \delta_n(x, s) \text{sgn}(v_n)dxds\).

Proof: We only prove the first inequality in Lemma 4. The second inequality can be assessed similarly. For \(\varepsilon > 0\), define

\[
\rho_\varepsilon(r) = \begin{cases} 
|\varepsilon|, & r > \varepsilon \\
\frac{-r^4}{8\varepsilon^3} + \frac{r^2}{4\varepsilon} + \frac{3\varepsilon}{8}, & |r| \leq \varepsilon
\end{cases}
\]

which is \(C^2\)-continuous in \(r\) satisfying \(\rho_\varepsilon(r) \geq |r|, |\rho'_\varepsilon(r)| \leq 1,\) and \(\rho''_\varepsilon(r) \geq 0\). Let \(\tilde{G}_n(x, t) = a_1(x) + \tilde{G}_{w_n}(t)\). By (20), (32), and (33), we have that

\[
\left|\tilde{G}_{n-1}(x, t)\right| \leq \|a_1\|_\infty + g_{n-1} \leq \frac{2\|a_1\|_\infty + g_{n-1}}{\delta_0} \int_\Delta |w_n|dx \tag{34}
\]

for any \((x, t) \in Q_T\). Multiplying \(\rho'_\varepsilon(w_n)\) to (21), and integrating by parts, we have

\[
\frac{d}{dt} \int_\Delta \rho_\varepsilon(w_n)dx = -\beta \|wnx\sqrt{\rho''_\varepsilon(w_n)}\|^2 + \int_\Delta wn\tilde{G}_{n-1}(x, t)\rho''_\varepsilon(w_n)wnx dx + \int_\Delta \delta_n(x, t)\rho'_\varepsilon(w_n)dx. \tag{35}
\]

We estimate the second term on the right-hand side of (35). By Young’s inequality, it follows:

\[
\int_\Delta wn\tilde{G}_{n-1}(x, t)\rho''_\varepsilon(w_n)wnx dx \leq \frac{1}{4\beta} \|wn\tilde{G}_{n-1}\|_\infty \|\rho''_\varepsilon(w_n)\|^2 + \beta \|wnx\sqrt{\rho''_\varepsilon(w_n)}\|^2 \\
\leq \frac{1}{4\beta} \|\tilde{G}_{n-1}\|_\infty^2 \|wnx\sqrt{\rho''_\varepsilon(w_n)}\|^2 + \beta \|wnx\sqrt{\rho''_\varepsilon(w_n)}\|^2. \tag{36}
\]

By (35) and (36), we have

\[
\frac{d}{dt} \int_\Delta \rho_\varepsilon(w_n)dx \leq \frac{1}{4\beta} \|\tilde{G}_{n-1}\|_\infty^2 \|wnx\sqrt{\rho''_\varepsilon(w_n)}\|^2 + \int_\Delta \delta_n(x, t)\rho'_\varepsilon(w_n)dx. \tag{37}
\]

Note that

\[
\|w_n\sqrt{\rho''_\varepsilon(w_n)}\|^2 = \int_\Delta w_n^2\rho''_\varepsilon(w_n)\chi_{\{|w_n| > \varepsilon\}}(x)dx + \int_\Delta w_n^2\rho''_\varepsilon(w_n)\chi_{\{|w_n| \leq \varepsilon\}}(x)dx \\
= \int_\Delta w_n^2\rho''_\varepsilon(w_n)\chi_{\{|w_n| \leq \varepsilon\}}(x)dx + \int_\Delta w_n^2 \frac{3(\varepsilon^2 - w_n^2)}{2\varepsilon^3}\chi_{\{|w_n| \leq \varepsilon\}}(x)dx \\
\leq \frac{3}{2}\varepsilon(x - x). \tag{38}
\]

By (34), (37), and (38), it follows:

\[
\frac{d}{dt} \int_\Delta \rho_\varepsilon(w_n)dx \leq \frac{3\varepsilon(x - x)}{4\beta} \|a_1\|_\infty + g_{n-1} \left(\int_\Delta |w_n|dx\right)^2 + \int_\Delta \delta_n(x, t)\rho'_\varepsilon(w_n)dx \\
+ \int_\Delta \delta_n(x, t)\rho'_\varepsilon(w_n)dx \\
= c_\varepsilon \left(\int_\Delta \rho_\varepsilon(w_n)dx\right)^2 + \int_\Delta \delta_n(x, t)\rho'_\varepsilon(w_n)dx. \tag{39}
\]

We infer from Gronwall’s inequality

\[
\int_\Delta \rho_\varepsilon(w_n)dx \leq \int_\Delta \rho_\varepsilon(w_0)dx \times e^{c_\varepsilon \int_0^t \int_\Delta \rho_\varepsilon(w_n(x, s))dxds} \\
+ \int_0^t \int_\Delta \delta_n(x, s)\rho'_\varepsilon(w_n(x, s))dx dx \times e^{c_\varepsilon \int_0^t \int_\Delta \rho_\varepsilon(w_n(x, t))dx dt}. \tag{40}
\]

Note that \(w_n\) is smooth and bounded on \(\Delta \times [0, T]\). Letting \(\varepsilon \to 0\), we get

\[
\int_\Delta |w_n(x, t)|dx \leq \int_\Delta |w_0(x)|dx + \int_0^t \int_\Delta \delta_n(x, s)\text{sgn}(w_n)dxds.
\]

Step 4: We prove that every constant of the estimates of \(w_n\) and \(v_n\) in the proof of Lemma 4 are independent of \(n\), i.e., we have the result stated in the following.

Lemma 5: Let \(w_n, v_n \in H^{2+\theta, 1+((2\theta)/2)}(Q_T)\) be the solutions to (21) and (22), respectively. For any \(n\), it holds

\[
\max_{Q_T} |w_n| \leq m, \quad \max_{Q_T} |v_n| \leq M, \quad |w_n(x^{(2+\theta)})| \leq M \tag{41a}
\]

\[
\max_{Q_T} |v_n| \leq l, \quad \max_{Q_T} |v_n| \leq L, \quad |v_n(x^{(2+\theta)})| \leq L \tag{41b}
\]
where \( M, \tilde{M}, \tilde{M}, L, \) and \( \bar{T} \) are positive constants independent of \( n \).

**Proof:** By the proof of Lemma 4 and \( \| \delta_n \|_\infty \leq 1 + \| \delta \|_\infty \), \( \| w_n(u, t) \|_1 \) is uniformly bounded in \( n \). Then, by the continuity of \( w_n \), we deduce that \( w_n \) is uniformly bounded in \( n \) on \( Q_T \). Note that \( \int_{Q_T} \beta \triangle u dt = \beta(w_n(x, t) - w_n(x, t)) \). By (32), (19b), Lemma 4, and the a.e. convergence of \( \delta_n \) to \( \delta \), we have that \( G_{w_n}(t) \) is uniformly bounded in \( n \) on \( Q_T \). Then, \( m_n, M_n \), and \( \bar{T}_n \) in (29) are all independent of \( n \). Therefore, (31a) holds. Equation (31b) is a consequence of the uniform boundedness of \( G_{w_n}(t) \) and [40, Ch. V, Th. 5.4 and 7.2–7.4].

**APPENDIX C**

**PROOF OF THEOREM 2**

Note that as (11b) is linear in \( v \), it suffices to prove that \( w_1 = w_2 \) in \( Q_T \). Letting \( \tilde{w} = w_1 - w_2 \), it follows:

\[
\frac{\partial \tilde{w}}{\partial t} = \beta \frac{\partial \tilde{w}}{\partial x} - \alpha_1(x) \tilde{w} - \tilde{w} G_{w_2}(t) - w_1(G_{w_1}(t) - G_{w_2}(t))
\]

By (42)–(44), Hölder’s inequality, and Young’s inequality, we have

\[
\frac{1}{2} \frac{d}{dt} \| \tilde{w} \|^2 \leq -\beta \| \tilde{w} \|^2 + \frac{e}{2} \| \tilde{w} \|^2 + \frac{e}{2} \| \tilde{w} \|^2 + \frac{C_2}{2\epsilon} \| \tilde{w} \|^2
\]

where \( \epsilon > 0, C_2 \) is a positive constant depending only on \( T, \| \omega \|_1, C_0, C_1, \) and \( \epsilon \). Choosing \( \epsilon = (2/3)\beta \), it follows:

\[
\frac{d}{dt} \| \tilde{w} \|^2 \leq C_3 \| \tilde{w} \|^2
\]

where \( C_3 \) is a positive constant. By Gronwall’s inequality, we have

\[
\| \tilde{w} (\cdot, t) \|^2 \leq \| \tilde{w} (\cdot, 0) \|^2 \cdot e^{C_3 t} = 0
\]

based on which and by the continuity of \( \tilde{w} \), it yields \( \tilde{w} \equiv 0 \) on \( Q_T \).
