# A STUDY OF THE PRELOAD RELATIONSHIP IN BOLTING TECHNOLOGY: EXPERIMENTAL DESIGN AND ANALYSIS. 

by<br>Bernard CLEMENT, Ph.D. and

André BAZERGUI, Ph.D. Eng.

Bernard Clément is professor, Dept. of Applied Mathematics. André Bazergui is professor, Dept. of Mechanical Engineering. Both are at Ecole Polytechnique, Montréal, Canada, H3C 3A7.

#### Abstract

This report presents the results of an exploratory investigation on preload funded by the Bolting Technology Council (BTC). Of the large number of factors that are thought to affect the torque/tension (preload) relationship, eleven factors, considered to be the more critical, have been selected for inclusion in the investigation. Using a statistical approach, a two-level screening experiment was thus designed. Simple experimental rigs were fabricated involving a single bolt with a combination of solid plates, spacers, Belleville springs, etc. to simulate different stiffness and installation conditions. A total of 64 tests were performed. Analysis of the results shows that the preload mean is affected by torque, axiality, bolt diameter and plating while the preload dispersion is related to installation method, lubricant, plating and diameter. The exploratory nature of the study must be taken into account when interpreting the results. Also, a duplicate series of tests is being funded by the BTC to confirm the present findings.

## 1. the engineering probley of preload in bolting

The problem of preload response in bolting technology is a complex phenomenon. In a document prepared for the Bolting Technology Council, Bickford (1987) lists a set of 54 parameters (factors) which affect the torque/tension (preload) relationship of a joint fastened together with threaded products. This information is shown in the Ishikawa diagram of Fig. 1.

Following a request for proposal by the Bolting Technology Council, the authors were awarded a contract to study the problem with a statistically designed experimental approach. This is an exploratory study whose objective is to screen, among the many factors identified above, the active factors from the inert ones.

A brainstorming session held in Montreal with A. Craig Hood, identified a subset of 11 critical factors together with their respective low and high values in order to carry out a two-level screening experiment. The 11 factors selected are listed in Table 1 and are also printed in bold letters in Fig. 1.

## 2. DESIGNED EXPERIMENTS

### 2.1 Screening designs

The theory and practice of statistically designed experiments is a vital and important subject for engineers, scientists and experimenters. In the last decade, there has been a tremendous growth of designed experiments, particularly in industry. Since 1983, for example, there is an annual symposium on Taguchi methods (experimental designs) for quality engineering.

From a practical point of view, the steps in designing exploratory screening experiments are straightforward. These are based on socalled Plackett-Burman designs also known as Hadamard matrix designs, $2^{k-p}$ fractional factorial designs, or Taguchi orthogonal arrays, see Wheeler (1988). These designs are based on a small number of runs suitably chosen, see Fig. 2 and Table 2.

These designs have many interesting properties and characteristics such as:

- A large number of factors may be investigated with a minimum of runs; $r$ factors can be studied in (r + 1) runs (saturated designs); for example, 127 factors can be screened in 128 runs;
- Each main effect is estimated independently of all other main effects and each is estimated with the same precision; this is related to the orthogonal property of the design;
- Main effects can be estimated and isolated from two-factor interactions by combining the basic design with its complementary (reflected or fold-over) design;
- The factors for which it is the hardest to change the levels are taken into account making it easier to carry out the experiment;
- The basic designs (geometric designs) have a number of runs $r$ equal to a power of 2 ,

$$
r=8,16,32,64,128 .
$$

Note: Higher values of $r$ are not used unless the study involves many hundreds of factors.

- There are also some intermediate designs (non-geometric) such as:

$$
\begin{aligned}
& r= 12,20,24,28,36,38,44,46,48,60,68,69,71,72,80, \\
& 81,84,93,143 .
\end{aligned}
$$

In a geometric design (i.e. $r=8,16,32 \ldots$ runs) there is a unique correspondence between an interaction and a main effect. For nongeometric designs ( $r=12,20,24, \ldots$ ) the confounding pattern is complex and is of little use in isolating individual effects. For this
reason, the non-geometric designs are less informative in a sequential research program. However, since the gaps between geometric designs get progressively larger, some of the larger non-geometric designs can be useful as the first of a sequence of experiments. Unless the number of factors is large (more than 20 , say) and the resources are scarce, it is preferable to use a geometric design.

A very important concept in the design of experiments is that of the Design Resolution as listed in Table 3. From a practical point of view, designs of resolution III and IV are the most useful for screening exploratory studies. It is also very easy to go from resolution III to resolution IV by folding over the basic design (i.e. using a reflected design, see below).

### 2.2 Designs for 11 factors

In our case, with 11 factors, a fully crossed experiment would require $2^{11}=2048$ runs. In such an experiment, all effects would be estimable:

> 11 main effects
> 55 two-factor interactions (first-order interactions)
> 1981 higher order interactions

In an exploratory study, we are not interested in high order interactions. In general, there are only a few active factors and many inert factors giving very few, if any, significant high order interactions. Moreover, time and/or cost considerations preclude even thinking of running an experiment with several thousand runs.

The alternate route is to opt for a fractional design approach in order to screen the active factors from the inert ones. Once this first stage experiment has been analyzed and if there is a need to estimate all of the effects, a full fractional experiment can then be performed on the active factors only.

From a practical point, the correct fractional factorial for screening purposes must be selected. In order to provide an answer to this question, the experimenter needs only to specify the design resolution. As a general rule, a resolution lll design is a good starting point and, if necessary, can be augmented to reach a resolution IV design. Rarely is there a need to go to resolution $V$ design in exploratory studies. Table 4 gives a set of candidate experimental designs for screening 11 factors.

### 2.3 Our experimental strategy

The following criteria have been retained for studying the selected 11 factors:
a) Simplicity of confounding pattern of main effects and interaction effects
b) Possibility of reaching resolution IV
c) Repeatability of results and analyses
d) Possibility of analyzing location measures and dispersion measures
e) Least number of runs
f) Sequential approach

Considering all of the above criteria, we have decided to:

- Start with the basic $16-r u n$ design since it is the smallest geometric design for 11 factors
- Combine the $16-r u n$ basic design with the reflected $16-r u n$ design to obtain resolution IV
- Replicate both the basic and reflected $\mathbf{1 6 - r u n}$ designs in order to satisfy criteria c) and d).

The details of each stage are given in Table 5.

## 3. THE SELECTED EXPERIMENTAL DESIGNS

### 3.1 Factor assignment for the basic $\mathbf{1 6 - r u n}$ design

Table 6 lists the 11 factors together with their low and high levels and their contrast label (letters A to 0 ). Note that the 16-run design can accommodate up to 15 factors, one for each label A, B,.., 0 . In our case we have 11 factors and the labels $1, J, L, O$ are not associated with any factors. These labels are used in the statistical analysis computations and they estimate pure interaction effects (Table 9).

### 3.2 The basic 16 run design

The basic 16-run design is outlined in Table 7. The high and low levels are indicated by + and - respectively. Note that the experiment is made easier by assigning the first, or leftmost contrast labels to those factors for which it is hardest to change levels. As an indication, the number of changes in level is also given in Table 7.

### 3.3 The reflected $\mathbf{1 6 - r u n}$ design

The reflected design is detailed in Table 8. Note that it is identical to Table 7 except that all signs have been inverted.

### 3.4 Confounding Patterns of Contrast

Table 9 lists the confounding patterns of contrast for the basic and reflected designs. Contrast label A, for example, estimates [A - BC -DE - FG] in the basic plan while in the reflected plan it estimates $[A+B C+D E+F G]$. Single letters indicate a main effects while double letters indicate an interaction. Note that each interaction is associated with a single contrast label.

Details on the statistical definitions and procedures are given in Appendices A, B, and C.

## 4. EXPERIMENTAL CONSIDERATIONS

Details of the experimental rig are given in Appendix D. It was specially designed for this experiment and consisted of two similar fixtures (one for the $3 / 8^{\prime \prime}$ fasteners, the other for the $3 / 4$ ").

A stack of steel blocks, solid washers and Belleville springs, and a load transducer make up a fixture. The different components may be readily interchanged for the appropriate run. The head of the bolt fits in appropriate slots at the base of the fixture which is itself fastened to a heavy steel mount. This allows the operator to work unassisted during the torquing operation.

Appendix D also discusses the way in which the high and low values of each of the test parameters were achieved together with specific comments. All of the tests were performed by the same operator, see Nadeau (1989).

## 5. DATA ANALYSIS AND DISCUSSION

The experimental results are given in Apendix A (Tables 10 and 11). The statistical approach is detailed in Apendices B and C. In order to illustrate the trends, a number of graphs and summary tables are given in Figs. 2 to 7 . Following are some details and discussion:

### 5.1 Central Tendency: Main Effects

Figure 2 shows the effect of each parameter taken individually. The table at the top of the figure lists the parameters in their order of importance while a schematic graphical representation is given at the bottom of the figure. While the overall mean value of pre-load is 62 $k s i$, torque, for example, affects it by $+/-31.6 \mathrm{ksi}$. The positive
slope on the graph indicates that the high or "+" value of torque produces a high value of pre-load. In the case of axiality, on the contrary, the high or "+" value is a $5^{\circ}$ bevel which produces a lower torque value; so here the pre-load range is $62-/+18.8 \mathrm{ksi}$ and the slope of the schematic line is negative.

The fact that Torque, Axiality, and Diameter are the three parameters with the greatest effect on pre-load is not too surprising. Plating, which comes fourth in line, influences surface finish and surface lubricity and its effect on pre-load is reasonable. Next in line come Number of tightenings, Grade of fastener, Installation method and Lubricant with almost the same effect each. In the case of the Lubricant, it should be noted that the "unlubricated" bolts were not cleaned before the test but were actually used in the "as-received" condition (i.e. they were probably covered with a light protective layer of oil). Surprisingly, Corrosion, Joint stiffness, and Thread engagement are found to have an almost negligible influence on preload.

### 5.2 Central Tendency: Interactions

Figure 3 lists, in their order of influence on pre-load, the different groups of interactions. The following pairs appear to be the best candidates for interaction effects:

| $C H: ~ P l a t i n g ~$ | and | Axiality |
| :--- | :--- | :--- |
| $H N:$ Axiality | and | Diameter |
| KN: Torque | and | Diameter |
| $C E:$ Plating | and | Grade |

The interactions are suggested by the factors having a significant main effect.

### 5.3 Dispersion: Main Effects

Figure 5 shows the dispersion in pre-load due to the parameters taken individually. The presentation is very similar to that of Fig. 2. The parameter which most influences dispersion is, as expected, the Method of Installation (i.e. hand vs impact wrench); as discussed in Appendix $D$, the impact wrench, in particular, was very difficult to adjust and did not give repeatable torque values. However, the revealing aspect is that Lubricant is next in line with regards to dispersion; considering its small influence on the central tendency, this would seem to indicate that the lubricant contributes little to the level of pre-load while producing more scatter. Plating also produces dispersion but it was also seen to affect the central tendency as well. The effect of the other factors on dispertion is relatively less pronouced; of interest is the fact that Torque produces the least dispersion.

### 5.4 Dispersion: Interactions

As indicated in Fig. 6, the interpretation is not straightforward but possible important interactions are:

| HN: Axiality | and | Diameter |
| :--- | :--- | :--- |
| AC: Corrosion | and | Plating |
| BC: Lubricant | and | Plating |
| BN: Lubricant | and | Diameter |

## 6. CONCLUSIONS

### 6.1 A Sumary of the Factors Importance

This invetigation started with eleven (11) factors thought to affect the pre-load response in a bolted joint. By using a set of 32 runs in a controlled screening experiment with a well chosen statistical design, we have been able to identify a first set of factors affecting the mean value of the response (torque, axiality, diameter, and plating) and a second set of factors affecting the dispersion of the response (installation, lubricant, plating, diameter).

Furthermore, we are suggesting that the following interactions are important: plating-axiality, diameter-axiality, torque-diameter, lubricant-plating, and lubricant-diameter.

Figure 7 illustrates the set of active factors in a joint fastened together with threaded products.

### 6.2 Further developments

At its meeting of June 6, 1989, the members of the Bolting Technology Council voted unanimously to fund a repeat experiment so as to verify the data and observations reported here. Phase ll of the project is presently in progress under the authors' supervision. Some important points regarding the new test scheme:

1. A new set of bolts ( $3 / 8$ and $3 / 4^{\prime \prime}$ diameter) is to be secured from a different supplier.
2. Two different experiments will be designed, one for each bolt diameter. This will increase the number of tests which will increase the resolution thus separating main effects from interaction effects.
3. A calibrated torquemeter will be used so as to reduce the uncertainly due to applied torque. Note that the use of calibrated torquemeters could imply that there is no point in running the series with the impact wrench. The number of factors would thus be reduced by one (to 10). One of three choices is presently being considered:
a) Work with 10 factors only, thus increasing the resolution especially with regards to the interaction effects.
b) Run the impact wrench series anyway
c) Select another factor

## ACKNOWLEEDGMENTS

Basic funding for this project was provided by the Bolting Technology Council. Its chairman, Mr. John H. Bickford provided excellent support and guidance throughout.
The various test fasteners were supplied by Lake Erie Screw Corporation (Lakewood, OH); many thanks to Mr. Steve Vass for his cooperation.
With his vast experience in bolting technology, A. Craig Hood's guidance was essential to this project.
The tests were performed by Jacques Nadeau as part of his final year undergraduate project in Mechanical Engineering at Ecole Polytechnique, Montreal. Jacques also contributed to the design the test rig. His engineering and technical skills are hereby acknowledged.

## APPENDIX A <br> DEFINITIONS AND EXPERIMENTAL RESULTS

Tables 10 and 11 give the experimental values and their derived statistical parameters for the basic and reflected designs, respectively. The following definitions apply:

```
A, B, ..., N, O: variables (see Table 6)
NAD1, NAD2 : preload in lbs (two replicates)
Y1, Y2 : preload in ksi (two replicates)
    Yj = NADj/77.5 if Diameter = 3/8
    NADj/334.0 if Diameter = 3/4
    with j = 1,2
    Note - The constants 77.5 and 334.0 are 1000 times the
    tensile stress areas (in}\mp@subsup{}{}{2}\mathrm{ ) for 3/8 and 3/4 diameter
    bolts, respectively.
YBAR = (Y1 + Y2)/2 : mean response
S' = (Y1 - YBAR )
    =(Y1 Y Y2)
LOG(S' ) : natural Log of variance
```

## APPENDIX B

## Statistical models for analysis

B. 1 Basic design model for the mean value of preload
$\bar{Y}_{\mathrm{i}}^{\mathrm{B}}=\beta_{00}+\beta_{\mathrm{A}} \mathrm{X}_{\mathrm{Ai}}+\beta_{\mathrm{B}} \mathrm{X}_{\mathrm{Bi}}+\ldots+\beta_{\mathrm{N}} \mathrm{X}_{\mathrm{Ni}}+\beta_{\mathrm{O}} \mathrm{X}_{\mathrm{Oi}}$
where
$\bar{Y}_{i}^{B}$ : Mean preload response (from 2 replicates) for run $i=1,2, \ldots, 16$
Superscript B refers to "Basic design"
$\beta_{o o}$ : overall effect
$X_{A i}, \ldots, X_{0 i}:$ columns (contrast labels) of the basic design for run i (see Table 10)
$\beta_{A}, \ldots, \beta_{0}$ : statistical parameters

The overall effect and the statistical parameters are estimated by:
$\hat{\beta}_{00}=\frac{1}{16} \sum_{i=1}^{16} \quad \bar{Y}_{i}^{B}=\bar{Y}^{B}$
$\hat{\beta}_{A}=\frac{1}{16}{\underset{i=1}{16}}_{X_{A i}} \bar{Y}_{i}^{B}$
$\hat{\beta}_{B}=\frac{1}{16} \sum_{i=1}^{16} X_{B i} \bar{Y}_{i}^{B}$

$$
\begin{aligned}
& B \\
& i
\end{aligned}
$$

$$
\hat{\beta}_{0}=\frac{1}{16} \sum_{i=1}^{16} X_{0 i} \bar{Y}_{i}^{B}
$$

where the ${ }^{\wedge}$ notation denotes an estimate.
As indicated in Table 9,
$\hat{\beta}_{A}$ estimates $[A-(B C+D E+F G)] / 2$
$\hat{\beta}_{\mathrm{B}}$ estimates $[\mathrm{B}-(\mathrm{AC}+\mathrm{DF}+\mathrm{EG})] / 2$
$\hat{\beta}_{0}$ estimates $[-(A N+B M+D K+G H)] / 2$
where $A, B, \ldots, O$ are the main effects for factors $A, B, \ldots, 0$, and $B C, D E, \ldots$ are the interaction effects. The analysis of the variance equation is given by:
$\sum_{i=1}^{16}\left(\bar{Y}_{i}^{B}-\bar{Y}^{B}\right)^{2}=16\left(\beta_{A}^{2}+\beta_{B}^{2}+\ldots+\beta_{N}^{2}+\beta_{0}^{2}\right)$

Note that, because of the orthogonal nature of the design,

$$
\sum_{i=1}^{16} X_{A i}^{2}=\sum_{i=1}^{16} X_{B i}^{2}=\ldots=\sum_{i=1}^{16} X_{0 i}^{2}=16
$$

and

## B.2. Reflected design model for the mean value

$\bar{Y}^{R}=\gamma_{00}+\gamma_{A} X_{A i}+\gamma_{B} X_{B i}+\ldots+\gamma_{N} X_{N i}+\gamma_{0} X_{0 i}$
where
$\bar{Y}_{i}^{P}$ : mean preload response (from 2 replicates) for run $i=1,2, \ldots, 16$
Superscript $R$ refers to "Reflected design."
$\gamma_{00}$ : overall effect
$X_{A i}, \ldots, X_{0 i}:$ columns (contrast labels) of the reflected design for run $i$ (See Table 11)
$\gamma_{A}, \ldots, \gamma_{O}:$ statistical parameters

The overall effect and the statistical parameters are estimated by:
$\hat{\gamma}_{00}=\frac{1}{16}{\underset{i=1}{16}}_{\bar{Y}_{i}^{R}}^{i=\bar{Y}^{R}}$
$\hat{\gamma}_{A}=\frac{1}{16}{\underset{i=1}{16} \quad X_{A i} \bar{Y}_{i}^{R}, ~}_{i=1}$
$\hat{\gamma}_{0}=\frac{1}{16}{\underset{i=1}{16}}_{\sum_{0 i}}^{\dot{Y_{i}}}$
and
$\gamma_{A}$ estimates $[A+(B C+D E+F G)] / 2$
$\hat{\gamma}_{B}$ estimates $[B+(A C+D F+E G)] / 2$
$\hat{\gamma}_{0}$ estimates $(A N+B M+D K+G H) / 2$

## B. 3 Main and Interaction Effects

By combining equations (2) and (6) we get, for the main effects,

$$
\begin{align*}
& A=\beta_{A}+\gamma_{A} \\
& B=\beta_{B}+\gamma_{B} \\
& \cdot  \tag{7}\\
& \cdot \\
& N=\beta_{N}+\gamma_{N}
\end{align*}
$$

While the interaction effects are given by:

$$
\begin{gather*}
\mathrm{BC}+\mathrm{DE}+\mathrm{FG}=\gamma_{\mathrm{A}}-\beta_{\mathrm{A}} \\
\mathrm{AC}+\mathrm{DF}+\mathrm{EG}=\gamma_{\mathrm{B}}-\beta_{\mathrm{B}} \\
\cdot  \tag{8}\\
\cdot \\
\mathrm{AN}+\mathrm{BM}+\mathrm{DK}+\mathrm{GH}=\gamma_{0}-\beta_{0}
\end{gather*}
$$

## B. 4 Model for preload dispersion

To identify the active factors related to the dispersion of the preload we have performed a similar analysis for the log of the sample variance $S^{2}$ :
$\log S_{i}^{2}=\beta_{00}+\beta_{A} X_{A i}+\beta_{B} X_{B i}+\ldots+\beta_{N} X_{N i}+\beta_{0} X_{O i}$
over the basic and reflected designs. Similar computations (Equations (2)...(8)) hold for the dispersion models. They are not given here.

## APPENDIX C <br> ANOM CHART

Four main factors are retained for the central tendency: torque (K), axiality (H), diameter (N) and plating (C). We have therefore 16 subgroups of size 2 from the combined data of the basic and reflected design. The values are given in Fig. 4.

The analysis of means (ANOM) is a graphical technique for comparing several means. The comparison is made via a chart similar to an XBAR and $R$ charts used in quality control. The details are given in Wheeler (1988).

The ANOM limits are computed from
$\overline{\bar{Y}} \pm H_{\nu, \alpha, k} \quad \overline{\overline{1}} \sqrt{\sqrt{n}} \quad \frac{R}{d_{2}^{\star}}$
where
$\overline{\bar{Y}}$ : is the overall mean or grand average
$H_{\nu, \alpha, k}$ : constants obtained from Table D in Wheeler (1988, p. 238)
$\nu:$ degrees of freedom (Table B, Wheeler 1988, p. 234)
$\alpha$ : significance level (0.05 say)
k : number of subgroups
n : sample size of subgroups
$\overline{\mathrm{R}}$ : average range
$d_{2}^{*}$ : constant depending on $n$ for bias correction (Table B, Wheeler 1988, p. 234)

In our case:

$$
\overline{\bar{Y}}=62, \nu=14, k=16, n=2, \overline{\mathrm{~A}}=11.3, \mathrm{~d}_{2}^{*}=1.15
$$

A control chart for the range gives an Upper Control Limit for R ( $U_{C L}$ ) :

$$
U C L_{R}=D_{4} \bar{R}=3.27 \times 11.3=37.0
$$

where $D_{4}$ is taken from Wheeler (1988) Table C, p. 236.

We see, for example that subgroup $1(K=+, H=+, N=+, C=+)$ is out of control (Figure 4).

After eliminating subgroups $1,5,7$ and 9 the remaining subgroups yield an average range $\bar{R}=4.81$ with an Upper Control Limit for $R$ :

$$
U C L_{R}=D_{4} \bar{R}=3.27 \times 4.81=15.7
$$

The contributing subgroups are all in control, so the unbiased estimate of the standard deviation for the pre-load is:

$$
\hat{\sigma}_{1}=\frac{\overline{\mathrm{A}}}{\mathrm{~d}_{2}^{*}}=\frac{4.81}{1.1}=4.4
$$

This estimate is in agreement with the average value of the variance $\left(S^{2}\right)$ of the basic and reflected designs:

$$
\begin{aligned}
& \bar{S}^{2}=21.0 \text { basic design } \\
& \bar{S}^{2}=17.1 \quad \text { reflected design } \\
& \bar{\sigma}=\left(\frac{21.0+17.1}{2}\right)^{1 / 2}=4.4
\end{aligned}
$$

The ANOM limits are computed from Equation (10):

$$
\begin{gathered}
\overline{\bar{Y}}=62, \quad \nu=14, d_{2}^{*}=1.15, \bar{R}=4.81, \\
n=2, \alpha=0.05, H_{\nu}, \alpha, k=3.40
\end{gathered}
$$

ANOM limits: $62 \pm 3.40 \frac{1}{\sqrt{2}} \frac{4.81}{1.15}=62 \pm 10$

These limits are represented by the horizontal dashed lines in Fig. 4.

We note that of all the 16 subgroups defined by $K, H, N$ and $C$ only subgroups $3,8,9$ are within the control limits (52 to 72). This indicates that they are not statistically different from each other.

## APPENDIX D EXPERIMENTAL DETAILS

This appendix is based on Jacques Nadeau's (1989) Mechanical Engineering final year undergraduate project.

## D.1. The Test Fixtures

Figure 8 shows the assembly drawing of a typical arrangement of one of the two fixtures built specifically for the present study. Each fixture is made up of the following groups of components:
a) The test fastener consisting of the bolt (item 4 in Fig. 8), the nut (10) and a solid washer (9). Most of these items were certified as indicated in Table 12. They were used only once in the test program.
b) A load cell (5) consisting of a short cylinder instrumented with strain gages in a full Wheatstone bridge arrangement. The load cell gives a combined strain reading which is only sensitive to axial load. Temperature variations, bending, and torsional effects are cancelled out. Each of the two load cells was calibrated on a precision hydraulic test machine. The gain of the bridge amplifier was adjusted so as to give a strain gage read-out in physical units of load (lbs).
c) The stack of plates or blocks representing the bolted joint (6, 7, 8, and 14). To satisfy the different test run requirements -- i.e. flexible vs rigid joint, straight vs misaligned (non-axial), full- vs half-thread engagement -- a number of different components were used:

- A lower plate (6).
- Parallel-faced or bevelled upper plates (7) of different thicknesses.
- A solid washer or a stack of Belleville spring washers (8). The Belleville springs selected had an ID larger than the OD of the test bolts, so a guide (13) was used for proper alignment. Discussion on the choice and arrangement of the Belleville springs is given in Section D. 2 below.
d) A gripping arrangement consisting of:
- A pair of lower grips (2) bolted to the test bench (1) with a total of four bolts (12). These grips are machined and installed in such a way as to be clear of the load cell (5) while preventing the head of the test bolt (4) from rotating during the torquing operation.
- A pair of upper grips (3) bolted to the lower grips (2) with a total of four bolts (11). These grips are designed to clamp the lower plate (6) of the test joint assembly.

Note that the gripping arrangement is designed in such a way that, by releasing the clamping bolts (11), the test bolted assembly easily slides out.
e) A heavy test bench (1) bolted to the floor.

Typical photographs are given in Figs. 9 to 12: Figure 9 shows the full set of test fixture components before assembly. The $3 / 4^{\prime \prime}$ diameter solid joint is shown in Fig. 10. The 3/8" flexible joint with Belleville springs is shown in Fig. 11 while Fig. 12 shows a misaligned $3 / 8$ " solid joint.

## D.2. Belleville Spring Arrangement

During the test fixture design phase, it was decided that the stiffness of the stack of Belleville springs should be about $50 \%$ of that of the test bolts, thus:

$$
\begin{aligned}
\mathrm{K}_{\text {bolt }} & =A E / L \\
\text { with } A & =\text { cross-sectional area of bolt using nominal diameter } \\
E & =\text { Modulus of elasticity }=30 \times 10^{6} \mathrm{psi} \\
L & =\text { nominal bolt length }=5^{\prime \prime}
\end{aligned}
$$

From equation (11) the stiffness of the $3 / 8^{\prime \prime}$ and $3 / 4^{\prime \prime}$ diameter bolts is computed as $2.78 \times 10^{6}$ and $10.6 \times 10^{6} \mathrm{lb} / \mathrm{in}$ respectively. So the required corresponding Belleville spring stiffnesses was: $1.39 \times 10^{6}$ and $5.3 \times 10^{6} \mathrm{lb} / \mathrm{in}$ respectively. Also, it was necessary that the springs be overdesigned so as not to compress them beyond their linear-elastic range.

On hand were a number of Belleville spring washers 2-1/4" OD x 1-3/8" ID $\times 3 / 8^{\prime \prime}$. Their stiffness was determined experimentally to be $2.8 \times$ $10^{6} \mathrm{lb} / \mathrm{in}$ and was thus well suited for our needs since, by using two such washers in either a series or a parallel arrangement (See Fig. 13), the following stiffnesses could be obtained:

$$
\begin{aligned}
& K(\text { series })=2.8 \times 10^{6} / 2=1.4 \times 10^{6} \mathrm{lb} / \mathrm{in} \\
& K(\text { parallel })=2.8 \times 10^{6} \times 2=5.6 \times 10^{6} \mathrm{lb} / \mathrm{in}
\end{aligned}
$$

So, a pair of washers were used in series in the $3 / 8^{\prime \prime}$ fixture and another pair was used in parallel in the $3 / 4^{\prime \prime}$ one. Each of the two fixtures was provided with a special sleeve for holding the Belleville washers in a centered position (ltem 13 in Fig. 8).

## D. 3 Test Parameters

Following are some specific details on the way the experimental factors listed in Table 6 were acheived. For each parameter, "low" and "high" values (or "-" and "+" levels) were defined.

## D.3.1 Corrosion (Factor A)

Low value: No corrosion. The test fasteners were used in their "asreceived" condition.

High value: As shown in Fig. 13 the test bolts were dipped in a solution containing $3.5 \%$ in weight of table salt in water. The bolts were immersed head down only up to one half of the anticipated thread engagement. Immersion time was 3 hours for the unplated bolts and 100 hours for the plated ones. The nuts and washers were not corroded.

## D.3.2 Lubrication (Factor B)

Low value: No lubrication. The test fasteners were used in their "as-received" condition. They were not cleaned with solvents.
High value: A thin coating of Molybdenum-disulfite (Molykote by Alpha Corp.) was applied to the threaded end of the bolts.

Note that in the the design of the experiments, the first factors are those that are subject to the least number of changes (see Tables 7 and 8). This is an important point with regards to testing lubricated vs unlubricated bolts. Nevertheless, before testing unlubricated bolts, the fixtures were thoroughly cleaned and de-greased to prevent contamination.

## D.3.3 Plating (Factor C)

Low value: Plain bolts, nuts and washers
High value: As indicated in Table 12, depending on their size and grade, the bolts, nuts and washers used were either zincyellow coated (Gr. 5 nad 8) or hot-dip galvanized (ASTM A-325 and a-490 bolts). The matching finish fasteners were always used as a group (nut, bolt, washer). See also D. 3.5 below.

## D.3.4 Tightenings (Factor D)

Low value: Full torque was applied once.
High value: Full torque was applied four times with an interval of about 5 seconds in between.
Note: During the early stages of the program, we considered the possibility of retorquing at increasing torque levels. This approach was found to be inconvenient, however, because it meant that the torque or impact wrenches, had to be reset after every tightening, resulting in loss of precision and repeatability. See also D.3.9 and D.3.10 below.

```
D.3.5 Grade (Factor E)
Low value: Grade 5 or A-325
High value: Grade 8
Note: As indicated in Table 12, in some cases we had to use a Grade A-563 nut with a Grade 8 bolt. In one case we used a Gr. A-563 nut with a Grade A-325 bolt. In all cases the washers were of the hardened type. The zincyellow chromate nuts had no lot numbers. All of the washers were hardened and tempered.
D.3.6 Stiffness of joint (Factor F)
Low value: With Belleville spring washers (see Section D. 2 above), Fig. 11.
High value: With solid blocks, Fig. 10.
D.3.7 Thread Engagement (Factor G)
Low value: Full thread engagement, Fig. 15.
High value: Half thread engagement, referring to the threads in the nut as shown in Fig. 15.
```

## D.3.8 Axiality (Factor H)

```
Low value: No misalignment.
High value: \(5^{\circ}\) of misalignment, using a wedged block as shown in Fig. 13. Note that the angle of \(5^{\circ}\) applies to the upper face of the wedged block. The hole was drilled to a diameter large enough to provide clearance as the bolt bends during tightening.
```

## D.3.9 Torque (Factor K)

```
Low value: \(50 \%\) of recommended seating torque (see below).
High value: \(75 \%\) of recommended seating torque.
Originally the high value was set to be \(100 \%\) of the recommended seating torque but this caused stripping of the threads when the fasteners were either corroded or assembled with half thread engagement. As a compromise, we set the high value to \(75 \%\) of full torque.
```

## D.3.10 Installation Method (Factor M)

Low value: With a torque-wrench.
Wrenches used: - "Norbar" SL1, capacity 6 to 40 ft-lbs ("click" type)

- "Snap-on," capacity 0-1000 ft-lbs ("dial" type).

High value: With an impact wrench.
Wrenches used: - CP 734 air wrench, $1 / 2^{\prime \prime}$-drive, capacity 25 to $280 \mathrm{ft}-$ lbs

- CP 772 air wrench, 3/4"-drive, (capacity rating unavailable)

In order to attain the required torque values with the impact wrenches with some degree of precision it was necessary to maintain a good control on each of the following:

- Pressure of air supply (from 50 to 100 psig).
- Wrench throttle valve position (arbitrary graduations, from 0 to 15 for small wrench, and from 0 to 9 for large one).
- Duration of torquing operation (from 2 to 22 seconds).

Through a series of trials involving practise fasteners, the level of each of the above was adjusted until the preload reading was about the same as that obtained by the respective torque wrenches. This turned out to be a tedious and difficult operation producing a large scatter in torque levels for the same set of parameters.

## D.3.11 Diameter of Bolt (Factor N)

Low value: 3/8" - 16
High value: $3 / 4^{\prime \prime}$ - 10
Refer to Table 12 for details.
